DBC Migration Monitor

Technical submission brief

Michael Owusu | O-Enterprises | London | 2 October 2026
Target: Meteora DBC track, 10,000 USDC first prize. Materials prepared locally; no submission or award is claimed.

Project summary

DBC Migration Monitor is the proposed developer-facing package of our existing Meteora DBC-to-DAMM v2 research and execution infrastructure. Built within O-Enterprises, the underlying prototype detects graduations, checks pool-role bindings, prepares predicted post-migration state for supported keeper migrations, and prices supported DAMM v2 pools from streamed account state using integer arithmetic. It is intended to help launchpad and trading-terminal developers understand migration state and quote provenance without treating missing evidence as a safety signal.

An archived 120-second validation sampled 200 updates: 166 had matching streamed state and comparable chain swap events, 33 transactions were unavailable, and one update had no swap event. Among the 166, 132 swap-math comparisons matched; the remainder were not applicable, unsupported or skipped partial fills. These are recorded results, not a fresh independent chain audit. Internal mainnet trials exist, but external adoption, commercial revenue and sustained profitability are not established.

The work predates this hackathon. Our dated October 1-2 development report records fast-ticket integration, streamed-state pricing, validation and execution-latency work during the current competition period. We will disclose the earlier foundation separately. The reusable toolkit and independent reviewer experience are being packaged; they are not yet a publicly launched developer service.

Commercial direction

The proposed product serves launchpad builders and trading-terminal developers that need migration context and supported pool quotes. Initial outreach would test demand with a small number of developer pilots. A managed feed or integration-support model is a hypothesis, not current revenue. No external users, paid pilots, partnerships or customer commitments have been established in the evidence reviewed.

Funding position

The founder states that the business is self-funded and has no debt; this is not independently audited here. The competition prize is non-dilutive prize consideration, not a 10,000 USDC grant request or a guaranteed award. Legal ownership of the code and the eventual award recipient must be confirmed before any declaration or licence grant.

Architecture and supported scope

Existing components

Migration discovery and admission: dbc_damm2_migration_feed.py and dbc_damm2_migration_admission.py.
Pool-role ticket checks: exec_fast/ticket_entry.py in the October fast-execution candidate.
Quote arithmetic: dbc_damm2_exact_math.py and exec_fast/pool_mirror.py.
Account-state monitoring: exec_fast/pool_state_stream.py.
Semantic evidence: dbc_damm2_semantic_events.py.
These are local source references, not published repository links.

Pricing boundary

The inspected pool_mirror module identifies support for concentrated liquidity, fee collection modes BothToken and OnlyB, dynamic fees off, zero compounding fee, and linear or exponential time-scheduled base fees. Unsupported configurations must remain explicit. The integer port names Meteora SDK revision 4638e724. This package does not claim full SDK equivalence or support for every DAMM v2 configuration.

State and finality

The development report records a move away from reconstructing price solely from pre-execution transactions toward Yellowstone pool-account updates. Processed updates offer timely state but do not prove finality; rollback, freshness, ordering and fallback handling remain important. Local arithmetic does not authenticate a supplied account image or guarantee a transaction will execute at the quoted price.

Separation from trading

The underlying system includes private execution and accounting machinery. This submission positions reusable monitoring and pricing components; it does not publish a trading strategy, wallet, signer or launch command. The included offline utility checks an aggregate evidence file only. It makes no RPC requests and cannot place trades.

Reviewer access

A clean repository, source attribution and judge access remain release gates. The inspected upstream SDK revision had no root LICENSE file and no licence field in package.json. That observation does not settle legal rights; attribution and redistribution permissions need review before releasing derived code. No private source has been distributed in this package.

Evidence and limitations

Retained aggregate evidence

Source: evidence/stream_vs_chain_20261001.json. The file records a 120-second observation, 3,156 account updates across 284 pools, and 200 sampled updates. Its problems array is empty. These are aggregate internal records, not a fresh third-party audit or a complete transaction-level corpus.

Comparison accounting

Of 200 sampled updates, 166 streamed states matched comparable chain swap events; 33 transactions were unavailable and one update had no swap event. Of the 166 comparable cases, 132 swap-math comparisons matched; 14 were not applicable, 16 were unsupported and four partial fills were skipped. No mismatch is reported within the comparisons performed. Coverage exclusions are not successes and these counts cannot establish an unconditional accuracy rate.

Other reported engineering results

The October report describes a nine-pool no-money ticket-path shadow with successful simulated buys. Building a wire while the feed tip is at migration slot +0 is not proof of same-slot inclusion. It also reports a 70,000-case SDK differential exercise, but the result log was not independently rerun or included here; that count is not used as a headline claim.

Economic and safety limits

Recorded mainnet trials include both gains and losses. The October 2 report records a 28-trade run with net -0.002390382 SOL and describes reconciliation to the chain. This package has not repeated that reconciliation and makes no profitability claim. One report breakdown lists 19 wins plus seven capped losses, leaving two trades unclassified; we do not infer a win rate from it. Liquidity can disappear before a protective exit executes. Migration evidence is not a token-safety rating.

Verification performed for this package

The aggregate file was copied byte-for-byte, its accounting identities were checked, and source hashes were recorded. The accompanying offline tests cover consistency checks and deliberate failures. They do not rerun the trading system, the chain comparisons, the SDK differential suite, or any historical full-suite claims.

Development and proposed prize use

Development disclosure

The DBC/DAMM v2 foundation predates 14 September 2026. The October 1-2 report records in-period work on keeper-ticket integration, streamed pool pricing, comparison evidence and latency improvements. The packaging, narrative and offline evidence utility were prepared on 2 October. A file hash identifies a reviewed snapshot; it does not independently prove when code was authored. The eventual submission must identify pre-existing work and the specific competition-period changes.

Proposed allocation

10,000 USDC total: reusable interfaces and documentation 4,000; fixture corpus and reproducible validation 2,000; bounded infrastructure and hosting 1,500; independent review and licensing work 1,500; developer pilots and integration support 1,000. These are planning estimates, not invoices, quotes or approved expenditure. No allocation is for trading capital.

Proposed eight week delivery

Weeks 1-2: settle source attribution, prepare a clean package and supported-layout documentation.
Weeks 3-4: publish reproducible fixtures, tests and failure semantics after review.
Weeks 5-6: produce a read-only integration example and validate freshness and reorganisation behaviour.
Weeks 7-8: seek external developer pilots, document feedback and issue a reviewed release.
These are future objectives contingent on resources, not completed deliverables or guaranteed pilot commitments.

Track and rules

The Meteora listing includes developer tooling among its suggested projects and prefers products with mainnet usage. Internal trials are not evidence of independent customers. The listing showed OPEN on 2 October, a 20,000 USDC pool and 10,000 USDC first prize, with a deadline of 13 October 2026 at 06:59 UTC (07:59 BST). Colosseum separately advertises 14 September to 12 October and requires prior-work disclosure; use 12 October as the planning target for its own entry.
